

COVID-19 vaccines do not impact IVF success

March 17 2022

(HealthDay)—Receipt of a COVID-19 mRNA vaccine does not affect

the ovarian response or pregnancy rates in in vitro fertilization (IVF) treatment, according to a study published online Feb. 25 in *Fertility and Sterility*.

Sarit Avraham, M.D., from Shamir Medical Center in Tel Aviv, Israel, and colleagues analyzed 400 patients (200 vaccinated women and 200 age-matched unvaccinated women) undergoing IVF during January to April 2021.

The researchers observed no difference between vaccinated and unvaccinated patients in mean number of oocytes retrieved per cycle (10.63 versus 10.72). For patients undergoing fresh embryo transfers (128 vaccinated patients and 133 unvaccinated), there was no difference seen in clinical [pregnancy rates](#) (32.8 versus 33.1 percent), fertilization rate, or the quality of transferred embryos. The groups were also found to be similar with respect to fertilization rates and the mean number of cryopreserved embryos in freeze-all cycles.

"Women should be vaccinated for COVID-19 prior to attempting to conceive via IVF treatments, given the higher risk of severe illness in [pregnant women](#)," the authors write.
