

Patients who are not prescribed opioids find more improvements in physical function, study

22 January 2016

Opioids such as morphine, codeine and Tylenol 3 can be effective for treating pain, however, a new University of Alberta study finds that patients with neuropathic pain taking opioids report no improvements in physical functioning compared to those who were not prescribed opioids.

"We studied patients with neuropathic [pain](#) from nerve injuries such as diabetic neuropathy and pinched nerves, and the ones who weren't prescribed any [opioids](#) had statistically lower disability and higher [physical functioning](#) scores," says Geoff Bostick, associate professor of physical therapy at the Faculty of Rehabilitation Medicine and lead author of the study published in *Pain Medicine*.

The study looked at 789 patients across Canada who provided baseline measures of self-reported function, and again at six and 12 months after

treatment. Adjusting for severity of the symptoms, the research showed physical functioning and disability did not improve in patients with [neuropathic pain](#) who were prescribed opioids compared with those who were not prescribed.

"Even though opioid medications can be a powerful pain killer, it does not necessarily mean improved function will follow—pain is not the only factor in determining function," explains Bostick.

"It can be difficult helping people move when they have pain, but as a physiotherapist I know the importance of physical function and we have to help find a way to promote movement, even if it is painful."

As a pain expert, Bostick understands the important role opioids play in the treatment of pain.

"Pain is very complex, and people experience pain at very different levels. Opioids can help people with [severe pain](#) be more comfortable, but if they are not also facilitating improved function, the impact of these medications on quality of life should be questioned."

While improving function despite pain is difficult, there is a way forward. His suggestion is for those who are experiencing [chronic pain](#) and are medically cleared for physical activity, to use a graded approach.

"If you want to move better, it requires careful measurement of your tolerance to activity.

"Instead of say, walking until you reach your pain limit, I tell patients to walk until they are at 50 per cent of their tolerance—walk and stop before the pain gets too bad. Each week, walking time is gradually increased. Over time, this tolerance will

slowly increase and so will physical function."
