

Using an electronic device to detect cavities early

2 November 2017

lesions on the biting surfaces of molars and premolars.

Mineral loss in [tooth enamel](#) is a significant change that leads to the development of cavities. The battery-powered ECD detects this early mineral loss before a cavity forms. In clinical trials conducted through Stony Brook School of Dental Medicine, the ECD was up to 96 percent accurate in detecting microscopic pre-cavity enamel lesions. Lead researcher Israel Kleinberg, DDS, PhD, DSc, believes that the device will emerge as a new paradigm in oral healthcare and may help dentists diagnose and monitor pre-cavitated lesions in [enamel](#) that cannot be detected by X-rays.

The Electronic Cavity Detection (ECD) System is a battery-powered device that may help dentists detect early signs of cavities well before tooth decay is revealed by X-rays. Credit: Stony Brook University

Imagine if dentists could find clear signs of tooth decay long before dental lesions turn into cavities and without using X-rays. A new device cleared for commercialization this month by the Food and Drug Administration (FDA) is a potential tool for dentists to do just that.

Developed and patented by researchers in the Division of Translational Oral Biology in the Department of Oral biology and Pathology at Stony Brook University School of Dental Medicine, and licensed to Ortek Therapeutics, Inc., the Electronic Cavity Detection (ECD) System uses electrical conductance to diagnose and monitor enamel
