

Physically active older veterans fall more, but hurt themselves less

Active older veterans fall more often than their more sedentary peers who never served in the armed forces, but they're less likely to injure themselves when they do, says a University of Michigan researcher.

A new study by Geoffrey Hoffman, U-M assistant professor of nursing, compared risks of noninjury falls and [fall-related injuries](#) in veterans and nonveteran populations, including whether risks differed according to [physical activity](#) and age. Historically, veterans are more physically active than nonveterans.

Using data from 11,841 veterans and 36,710 nonveterans in the 2006-2015 waves of the Health and Retirement Study at the U-M Institute for Social Research, the study found that veterans had 11% more noninjury falls but 28% fewer injurious falls than nonveterans.

"The inference is that being active puts you at more risk for a fall, but if you are more active/in shape, the fall is more likely to be a minor one and not a serious one resulting in injury," Hoffman said.

"A worthwhile trade-off, arguably."

While the risk of noninjury falls increased more with age for veterans than for nonveterans, physical activity was more protective against a noninjury fall for veterans. Hoffman said that because veterans are nearly 100% male, there's not enough data to definitively state if the findings apply to all physically [active men](#), or just veterans.

This research is important because as people age, it's critical to find a good, healthy balance between physical activity and fall risk, Hoffman said.

"Personally, I'd rather not be the older adult who feels it's best to always sit on my couch because I'm too afraid of having a fall, so that when I do fall, it's really serious," he said.

Lack of physical activity carries both emotional and physiological health risks for [older adults](#), including metabolic problems like diabetes, obesity and [high blood pressure](#), and social isolation and depression.

Hoffman said older adults reap the benefits of physical activity from when they were younger, but veterans may benefit even more. It could be that vets have accumulated "health capital" from active lifestyles, including military training and activities while younger. There was also evidence that, even among active older adults, veterans are still more active than nonveterans.

"In an ideal world, we'd hope that you could get the benefits of being active, such as well-being, fitness and happiness, while avoiding all risk and having no falls," Hoffman said. "It seems more probable that being active is, in the longer-term, often protective against serious injury from falls. Maybe when you're active, a fall isn't as risky because you're in better shape, even while physical activity marginally increases nonserious fall risk."

"That's important, I think. A good trade-off can be made: more activity and independence at the cost of some more minor falls. It's up to each older individual with the input of family caregivers to weigh those trade-offs."

The bad news, Hoffman said, is that after a certain age, there's a point of diminishing returns, and the physical activity benefit disappears for even the most active veterans. It's unclear why or at what age physical activity stops having a protective effect.

The study looked primarily at men, but it's "entirely plausible" that the relationship between falls and injury and physical activity also exists in women, Hoffman said.

The study defined moderate activity as gardening, walking at a moderate pace, stretching exercises or home repairs, and vigorous activity as jogging, swimming, tennis or heavy housework.
