

Ketones buy time for a failing heart but are just more fuel for a healthy one, says study

In 2015, researchers began noticing that a drug used to treat Type 2 diabetes, empagliflozin, came with the added benefit of decreasing hospitalization for heart failure and death from cardiovascular causes in those patients.

"It was very unexpected, because this drug is targeted and marketed for

Type 2 diabetes, not heart failure," said Kim Ho, a pediatrics Ph.D. student in the Faculty of Medicine & Dentistry and recipient of the 2020 Izaak Walton Killam Memorial Scholarship, one of the most prestigious awards for University of Alberta doctoral students.

"It was just such a huge finding, but how is this drug that works in the kidneys helping the heart?"

One of the leading theories, according to Ho, was that the diabetes drug increased [ketone levels](#).

Ketone increases are more widely associated with a fad diet born out of an effective treatment for epilepsy—a high-fat, low carbohydrate food intake that forces the body to convert fat into ketones to use as an [energy](#) source instead of glucose from carbohydrates.

In this case, however, Ho said it was believed that if a side-effect of this drug was an increase in ketones in the blood traveling to the heart, these ketones might be the key to improving cardiac metabolism.

"There's been a theory put out there by some scientists that ketones are a thrifty [fuel](#) because it is more efficient than using fats or carbohydrates and thus, ketones can increase cardiac efficiency. That theory is flawed, though," she said.

Studies began popping up that confirmed a failing heart will switch over to ketones for energy. "Nobody knew why and what the cause was, because it was just a phenomenon they observed."

Searching for a thesis within cardiac metabolism, Ho wondered: if a healthy or diseased heart is given increasing amounts of ketones, does that really improve efficiency?

"Are ketones good or bad for the heart? That's essentially my thesis."

The first thing Ho looked at was the metabolic rate in the heart during heart failure.

Ho likens a failing heart to a car running out of fuel. While a normal heart relies on fat and carbohydrates for 60 percent of its energy, a failing heart is running out of those energy stores, but rather than stop, it increasingly relies on ketones.

"The heart needs fuel just like a car engine, and it uses these fuels—carbohydrates, fats, ketones, phosphates, amino acids—to basically fuel contractile function to pump blood throughout your body," she said.

Her supervisor, cardiovascular researcher Gary Lopaschuk, is a world-leading expert in cardiac metabolism, and his lab is renowned for carrying out isolated working heart perfusions. The technique involves taking a beating heart and pumping it with different simulated bloods to measure how efficient the heart is at using different types of energy.

Through this method, Lopaschuk's lab became the first to use direct methods to confirm that the cardiac metabolic rate of ketone use goes up during heart failure, though this was not accompanied by an increase in cardiac efficiency.

Knowing this, researchers can approach ketones as a potential therapeutic strategy by improving cardiac energy production in settings where energy production is decreased, such as during heart failure, Ho said.

What if increasing doses of ketones affect cardiac efficiency in a healthy heart, as the thrifty fuel hypothesis suggests? Better cardiac efficiency in

a healthy heart could mean anything from warding off heart disease to boosting athletic performance.

However, what Ho found was that ketones don't increase cardiac efficiency in a healthy heart.

As her team fed the heart higher concentrations of ketones, cardiac efficiency tended to decrease, although overall energy production in the heart increased.

"You would think that as you keep giving a heart more and more of a fuel, there's something that's going to regulate how much of this fuel the heart is using, but it just kept using more and more ketones to the point where ketones were the main fuel the heart was relying on," she said.

Reconciling the way in which ketones decrease cardiac efficiency but improve energy production in both a healthy and [heart failure](#) setting is difficult at this time, Ho said. Though there may be clear benefits to improving energy production when a heart is failing and starved for energy, the benefits for a healthy heart in "times of plenty" are less clear.

However, Ho underlined the significance that ketones do not increase cardiac efficiency in either a [healthy heart](#) or failing heart.

She also noted the research "also underscores the importance of recognizing ketones as a major fuel source for the [heart](#) in times of starvation, consumption of a ketogenic diet or poorly controlled diabetes."
